

Environmental monitoring in the demolition of the Vicente Calderon Stadium

CLIENT

AFC Ingenieros

SECTOR

Works & Demolitions

LOCATION

Madrid, Spain

PRODUCTS

Kunak AIR
Kunak AIR Cloud

Need

According to the indications of the Madrid City Council, firms in charge of demolition works must carry out environmental monitoring in their works to ensure the air quality in the zones where those works are being done.

These are places where a more vulnerable population live (among others, schools and sports facilities) and whose health is even more delicate than average.

It is necessary to offer tools that allow monitoring the effects on air quality derived from demolition and construction works that offer reliable and quality information that facilitate its control and environmental monitoring.

For this reason, AFC Ingenieros contacted Kunak in order to develop a solution capable of measuring reliably and accurately and offering a system of alerts when thresholds are exceeded.

Demolition works must carry out environmental monitoring in all their works to ensure the air quality in the zones where those works are being done

Solution

Deployment of a Kunak AIR sensor network with embedded wireless communications for monitoring parameters of polluting gases, particulates and noise pollution in real time.

The objective was to monitor emissions at demolition sites to control pollution levels. Thanks to the Kunak AIR Cloud platform, the data collected by the network is visualised and analysed in order to take corrective measures for those actions that exceed the permitted levels. In addition, thanks to the web platform, the operational management of the sensors that made up the network was carried out.

Results

Development of an environmental monitoring solution with the following features:

- Real-time alarms, alerts and statistics system.
- Detection of increased pollution episodes.
- Remote calibration and management of devices.
- Development of advanced statistical protocols to obtain high-quality and reliable data with high correlations with official stations and reference equipment.

Benefits

- Monitoring of emissions during the demolition.
- Real-time information on concentrations for decision-making.
- Monitoring PM concentrations in surrounding communities.
- Evaluation of the efficiency of the control systems in place.
- Monitoring and control of supplier emissions during the loading and unloading of materials.
